

π ε χ ε π Ph

Add-On Designs

 Were extensively discussed at the Bio-International '92 Conference, Bad Homburg, Germany

- Sometimes (rarely) accepted in the US and EU
- Implemented in Canadian (1992, 1996) and Japanese guidelines (1997, 2006)
- Only if planned, same protocol, batches, clinical and analytical method.
 If first part not BE, recalculation of sample size, initiation of second part.
- Pooling of both parts under certain conditions.

Add-On Designs

Canada

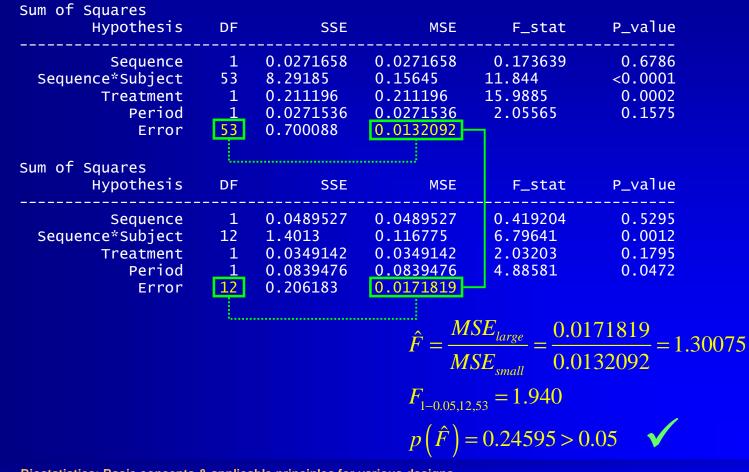

Second part in at least 12 subjects. Pooling is only allowed if two consistency tests not significant (*p*>0.05):

- Equality of residual mean squares (*F*-test) of the two parts.
 Smaller MSE must be used as the denominator.
 - Example:
 - 0.01321 (1st part: n=55, df 53)
 - 0.01718 (2nd part: n=14, df 12)

ε

Add-On Designs

Add-On Designs

Canada cont'd

Second part in at least 12 subjects. Pooling is only allowed if two consistency tests not significant (*p*>0.05):

 Since first test not significant (p 0.246), pool studies. Now test for study by formulation interaction. ANOVA model:
 Fixed: Study + Treatment + Treatment × Study

Random: Subject(Study) + Period(Study)

3

Add-On Designs

Canada cont'd

- Formulation by study interaction not significant (p 0.735), pooled analysis acceptable.
- No *α*-adjustment mentioned in 1992 guideline, but recommended in 2010 draft (Bonferroni: 95% CI).
- 2010 draft also allows for a group sequential design.

Add-On Designs

Japan

ε χ ε

- Sample size of first part ≥20 or sample size of both parts ≥30
- Sample size of second part ≥50% of first part
- Study must be added as a source of variation in the pooled analysis
- PE of the pooled study within 90% 111%
- Similar dissolution between test and reference
- No α-adjustment (90% CI).
 I would strongly recommend to use the 95% CI instead of the conventional 90% CI.

Add-On Designs

- It was shown in simulations that the patients' risk in naïve pooling may be inflated up to ~30%!
- Group sequential designs are a well known design in Phase III studies.
- •These designs test for a significant difference, *i.e.*, the null hypothesis is formulated differently to the one applied in BE.
 - Led to work on sequential designs in BE; LA Gould (1995) and D Potvin *et al.* (2008).

ε χ

Sequential Designs

- have a long and accepted tradition in later phases of clinical research (mainly Phase III).
 - Based on work by Armitage *et al.* (1969), McPherson (1974), Pocock (1977), O'Brien and Fleming (1979) and others.
 - First proposal by LA Gould (1995) in the area of BE did not get regulatory acceptance in Europe, but
 - stated in the current Canadian draft guidance (January 2010).
 - Two-Stage Design acceptable in the EU (GL 2010, Section 4.1.8) and the US (personal communication with Barbara Davit, Ljubljana, May 2010).

χ ε

Sequential Designs

Penalty for the interim analysis (94.12% vs. 90% CI) Moderate increase in sample sizes

- Example: T/R 95%, power 80%
- ~10–20% increase (sims by Gould 1995, Potvin 2008)

Comparison to a fixed

CV% 90% CI 94.12% CI ratio 1.00010 8 8 15 12 14 1.167 1.200 20 20 24 1.214 25 28 34 48 1.20030 40

sample design is based on a delusion – assuming the CV to be 'known'!
On the long run (many studies) sequential designs will need *less* subjects.

Sequential Designs

•LA Gould (1995)

Overall *α*-level preserved at ≤0.05. Individual Cl level ~93%–94% (calculation rather complicated; dependent on PE and sample size ratio of Stages).
 Multiple Stages (*i.e.*, >2) possible.

Canada's draft (2010)

- Maximum total sample size (Stages 1+2) and size of Stage 1 fixed in protocol.
- Adjusted α -levels stated in the protocol.

Two-Stage Design

•EMA GL on BE (2010)

Section 4.1.8

'Internal Pilot Study Design'

- Initial group of subjects treated and data analysed.
- If BE not been demonstrated an additional group can be recruited and the results from both groups combined in a final analysis.
- Appropriate steps to preserve the overall type I error (patients' risk).
- Stopping criteria should be defined a priori.
- First stage data should be treated as an interim analysis.

Two-Stage Design

•EMA GL on BE (2010)

Section 4.1.8 (cont'd)

Both analyses conducted at adjusted significance levels (with the confidence intervals accordingly using an adjusted coverage probability which will be higher than 90%). [...] 94.12% confidence intervals for both the analysis of stage 1 and the combined data from stage 1 and stage 2 would be acceptable, but there are many acceptable alternatives and the choice of how much alpha to spend at the interim analysis is at the company's discretion.

χ ε

Two-Stage Design

•EMA GL on BE (2010)

Section 4.1.8 (cont'd)

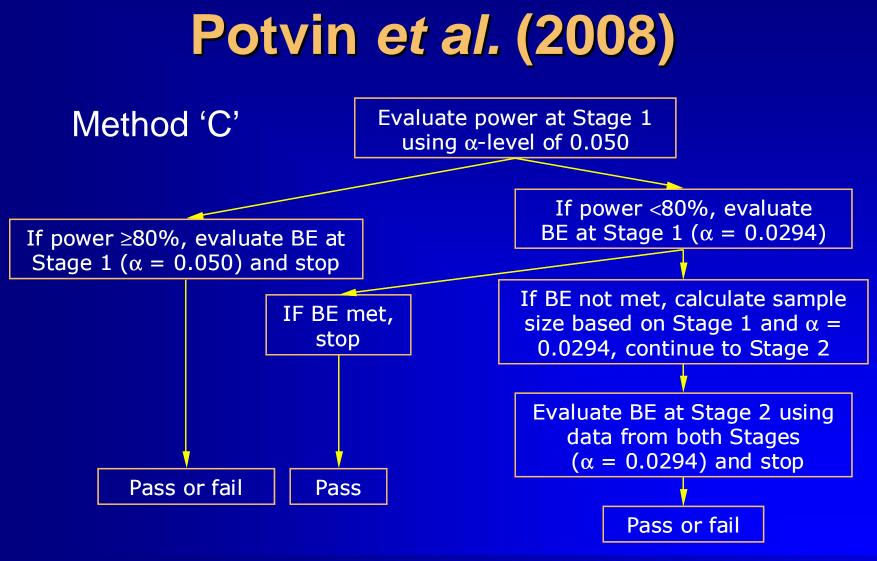

- Plan to use a two-stage approach must be prespecified in the protocol along with the adjusted significance levels to be used for each of the analyses.
- When analysing the combined data from the two stages, a term for stage should be included in the ANOVA model.

Two-Stage Design

- •Method by Potvin et al. (2008) promising
 - Supported by 'The Product Quality Research Institute' (members: FDA-CDER, Health Canada, USP, AAPS, PhRMA,...)
 - Acceptable by US-FDA
 - Acceptable as a Two-Stage Design in the EU
 - Three of BEBAC's protocols already approved by German BfArM

χ ε

Potvin et al. (2008)

Technical Aspects

- Only one Interim Analysis (after Stage 1)
- If possible, use software (too wide step sizes in Diletti's tables)
- Should be called 'Interim Power Analysis'; not 'Bioequivalence Assessment' in the protocol
- No a-posteriori Power only a validated method in the decision tree
- No adjustment for the PE observed in Stage 1
- No stop criterion for Stage 2! Must be clearly stated in the protocol (may be unfamiliar to the IEC, because standard in Phase III).

Potvin et al. (2008)

Technical Aspects (cont'd)
Adjusted α of 0.0294 (Pocock 1977)
If power is <80% in Stage 1 and in the pooled analysis (data from Stages 1 + 2), α 0.0294 is used (*i.e.*, a 1-2×α = 94.12% CI is calculated)
Overall patients' risk is preserved at ≤0.0500

Potvin et al. (2008)

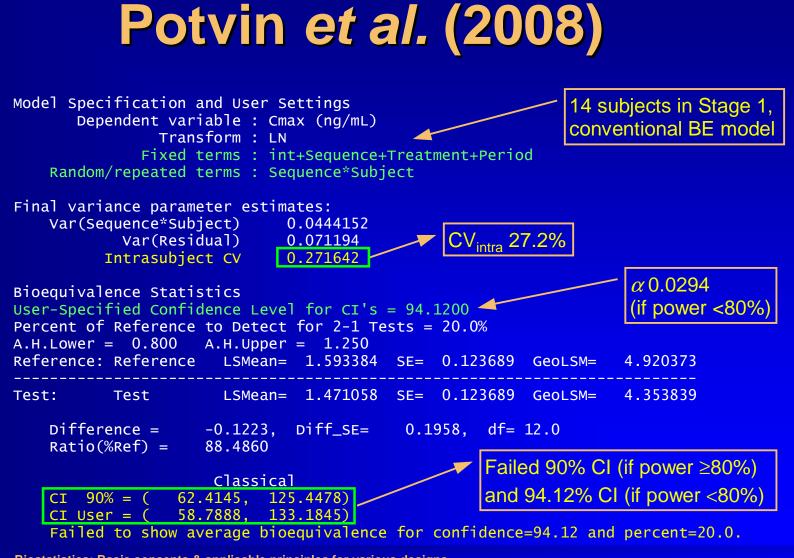

Technical Aspects (cont'd)

- If the study is stopped after Stage 1, the (conventional) statistical model is: fixed: sequence + period + treatment random: subject(sequence)
- If the study continues to Stage 2, the model for the combined analysis is: fixed: sequence + stage + period(stage) + treatment random: subject(sequence × stage)
- No poolability criterion; combining is *always* allowed – even for significant differences between Stages.

To bear in Remembrance...

The sample size calculation is an excuse for a sample size and not a reason. Stephen Senn

Science is a way of trying not to fool yourself. The first principle is that you must not fool yourself, and you are the easiest person to fool.

Richard Feynman

If you obey all the rules, you will miss all the fun. *Katherine Hepburne*
